

```

#include <iostream> // Header file for input and output
using namespace std;
// Class definition
class Student
{
private:
    static int count; // Static data member (common for all objects)
public:
    // Constructor
    Student()
    {
        count++; // Increment count whenever object is created
    }
    // Static member function
    static void showCount()
    {
        cout << "Total number of students: " << count << endl;
        // Static function can access only static data members
    }
};
// Initialization of static data member
int Student::count = 0;
// Main function
int main()
{
    Student s1; // Create first object
    Student s2; // Create second object
    Student s3; // Create third object
    // Call static member function using class name
    Student::showCount();
    return 0; // End of program
}

```

Output:

Total number of students: 3
